To achieve the performance of conventionally manufactured components, additively manufactured components have to fulfill at least the same requirements. This includes the possibility of functionalized surfaces with coatings and of being able to realize a sufficient fatigue strength of the overall system (component/coating). In the present project, therefore, the effects of residual stress and surface roughness, known as the restriction of the SLM process, on the coatability are fundamentally examined and the dynamic strength of the overall system is considered.

**PROJECT OVERVIEW**

**DURATION**
04/2017 – 03/2020

**PARTNER**
Institute of Materials Engineering, TU Dortmund

**FUNDED BY**
German Research Foundation (DFG)

**RESEARCHER**
Dipl.-Wirt.Ing. Leif Hagen
Kai-Uwe Garthe, M. Sc.
Research Assistant
Prof. Dr.-Ing. habil. Mirko Schaper
Prof. Dr.-Ing. Wolfgang Tillmann
Research Leader
Kai-Uwe Garthe, M. Sc.
Dipl.-Wirt.Ing. Leif Hagen

**Objectiv**

This project investigates the effects of residual stresses and surface roughness of additively manufactured components on the coatability and fatigue properties of the composite system (=coated component). The materials 316L and IN718 are analysed. In this context, the aim of these investigations is to achieve a qualitative statement regarding the effects of residual stresses and roughness on the coatability. This includes the determination of the adhesion strength of the coating as well as the generation of coating optimized SLM- and post-processing parameters, which guarantee a gap- and pore-free bond with high cohesion and adhesion. Further goals are the determination of the fatigue strength, the identification of failure mechanisms as well as the crack origin. Therefore, a fundamental understanding of both, the process and the combination of the advantages of both process steps to substitute further process steps, such as metal-cutting surface treatments, is mandatory. Based on a better understanding of the process, the quality of the additive components should also be optimized to such an extent that at least the level of conventional cast or forged components is reached.

**Approach**

First, for the manufacturing of the samples a parameter adaption is carried out. Subsequently, established sample geometries for fatigue tests (dog bone samples for room temperature and cylinder samples for 850 °C) are produced. The investigation of the manufacturing parameters ensures definable sample properties with a negligible porosity for a robust process and reproducible mechanical properties. After the production, all samples are examined regarding roughness, residual stress and porosity. This is followed by a pre-treatment using grinding or corundum blasting with a subsequent additional characterization of the roughness and residual stresses. The effects of the respective pretreatment methods on the surface are measured and correlated. Untreated samples (with and without heat treatment) are carried along as reference. Furthermore, half of the samples are coated via atmospheric processes (with and without heat treatment) are carried along as reference. The adhesion strength of the coating as well as the generation of coating optimized SLM- and post-processing parameters, which guarantee a gap- and pore-free bond with high cohesion and adhesion. Further goals are the determination of the fatigue strength, the identification of failure mechanisms as well as the crack origin. Therefore, a fundamental understanding of both, the process and the combination of the advantages of both process steps to substitute further process steps, such as metal-cutting surface treatments, is mandatory. Based on a better understanding of the process, the quality of the additive components should also be optimized to such an extent that at least the level of conventional cast or forged components is reached.

**Results**

In order to investigate the influence of the different pre- and post-treatments (grinding, blasting, heat treatment and coating) on the low cycle fatigue, fatigue tests are carried out. Here, the additively manufactured 316L samples (different states) are fatigued at a total strain amplitude of 0.35 %, a strain rate of 6*10^-3 s^-1 and at R = -1 at room temperature. Figure 1 shows the low cycle strength of ground 316L specimens (different states) without coating at a strain amplitude of 0.35 %. Based on the results it can be seen that grinding with a finer grain size leads to a better surface quality, and therefore to better fatigue properties. Furthermore, it can be seen that heat-treated samples exhibit the same tendencies, but with higher numbers of cycles. This can be explained by the fact, that the performed heat treatment reduces residual stresses, which are known to have a negative effect on the fatigue behaviour. Figure 2 summarizes the low cycle strength of ground 316L specimens (different states) with an Al2O3 coating at a strain amplitude of 0.35 %. The results reveal that an additional Al2O3 coating ensures a further increase of the low cycle strength. This trend does not apply to the heat-treated samples for the layer adhesion in this state is too low. It can be assumed that the residual stress condition has a negative effect on the adhesion.

**Outlook**

The restrictions currently present in the SLM process, such as porosity, residual stresses and surface roughness, are to be minimized based on the investigations carried out in this project. Therefore, a general improvement in fatigue life for 316L and Inconel 718 SLM components is achieved. Furthermore, a correlation between the adhesion of different coating materials and the different coating processes regarding their influence on the long-term fatigue of SLM components is addressed in the final period of the research project. The results are then correlated with post-treatment methods, like coating processes and the material pairing, with the aim to specify a critical criterion for adhesion. This approach is very important because a coating, allows non-corrosion resistant materials to be coated with a corrosion resistant material or for example to make it wear resistant.
